

1. The definition of logarithm is if  $a^x = y$ , then  $\log_a y = x$ , and if  $\log_a y = x$ , then  $a^x = y$ .
- a. Complete the tables for an exponential function base 10 and a logarithmic function base 10.

x	$10^x$
0	$10^0 = 1$
1	$10^1$
2	$10^2 = 100$
3	$10^3 = 1000$
4	$10^4 = 10000$
5	$10^5 = 100000$
6	$10^6 = 1000000$
7	$10^7 = 10000000$
8	$10^8 = 100000000$
9	$10^9 = 1000000000$
10	$10^{10} = 10000000000$

y	$\log_{10} y$
1	0
10	1
100	2
1000	3
10000	4
$10^5$	5
$10^6$	6
$10^7$	7
$10^8$	8
$10^9$	9
$10^{10}$	10

- b. Ten raised to what power is 1,000,000?  
Ten raised to the sixth power is 1,000,000.
- c. How can the definition of logarithms help you find  $\log_{10} 1000000$ ?  
 $\log_{10} 1,000,000$  is asking the question, "Ten raised to what power is 1,000,000?"
- d. Using the table, estimate  $\log_{10} 99,932$  to the nearest whole number.  
 $\log_{10} 99,932$  is asking the question, "Ten raised to what power is 99,932?" An exponent that is a little less than 5 is the solution since  $10^4$  is 10,000 and  $10^5$  is 100,000. The best whole number estimate would be 5.
- e. Using the table, estimate  $10^{3.1}$ .  
 $10^3$  is 1000 and  $10^4$  is 10000.  $10^{3.1}$  is closer to  $10^3$  than  $10^4$ , so 1200 is a good estimate.

2. Complete the tables below. The base is **three** in both tables.

x	$3^x$
0	1
1	3
2	9
3	27
4	81
5	243

y	$\log_3 y$
1	0
3	1
9	2
27	3
81	4
243	5

a. Without using a calculator, compute the following base **three** logarithms.

i)  $\log_3(81) = 4$

$$3^4 = 81$$

ii)  $\log_3(243) = 5$

$$3^5 = 243$$

iii)  $\log_3(1) = 0$

$$3^0 = 1$$

iv)  $\log_3\left(\frac{1}{3}\right) = -1$

$$3^{-1} = \frac{1}{3}$$

v)  $\log_3\left(\frac{1}{9}\right) = -2$

$$3^{-2} = \frac{1}{9}$$

3. Moore's Law states, informally, that the computing power of a chip doubles every two years.

a. Make a table showing how the computing power of a chip increases, where  $n$  is the number of doubling periods.

$n$	$2^n$
0	1
1	2
2	4
3	8
4	16
5	32
6	64

b. According to Moore's Law, how long will it take the computing power of a chip to increase by a factor of 64?

This question can be rewritten, what is the value of  $n$  if  $\log_2 64 = n$  (where  $n$  is the number of doubling periods). Since  $2^6 = 64$ ,  $n = 6$ . So, there will be 6 two-year periods which totals 12 years.

- c. According to Moore's Law, by what factor will the computing power of the chip increase in 16 years?

This question can be rewritten, what is the value of  $f$  if  $\log_2 f = 8$  (where  $f$  is the factor of increase of the computing chip)? Note that 8 is the number of two-year periods for 16 years. The computing power of the chip is increased by a factor of 256 ( $f = 2^8$ ).

4. Assume the population ( $p$ ) of a virus in a human body triples every hour.

- a. If we start with 1 virus in a body, how many will there be in three hours?

t	$3^t$
0	1
1	3
2	9
3	27
4	81
5	243
6	729

Use the equation  $\log_3(p) = t$ , where  $t$  is the number of hours and  $p$  is the population of the virus. For this problem we need to find  $\log_3 p = 3$ . Rewriting,  $3^3 = p$ , or  $27 = p$ . So, the population of the virus is 27 in three hours.

- b. How long will it take for the population of viruses to be 243?

In the equation  $\log_3 243 = t$ ,  $t = 5$  hours. It may be helpful to think of  $3^t = 243$ . It will take 5 hours for the population of viruses to be 243.

- c. How many viruses will there be in one day?

This can be represented as  $\log_3(p) = 24$ . Note that 24 hours is used instead of one day since  $t = \text{hours}$ . Rewriting the equation using the definition of logarithms  $3^{24} = p$ , or  $p = 282,429,536,481$  viruses.

- d. Is the equation below a valid representation for the number of viruses in a human body? Why or why not?

$$t = \log_3(p) \quad (t = \text{time in hours}, p = \text{population})$$

Yes, since  $p = 3^t$ , we have  $\log_3(p) = t$ .

5. The following is a graph of  $y = 4^x$ . Use the graph to estimate  $\log_4(8000)$ .  
Express  $\log_4(8000)=x$  in exponential form by using the definition of logarithms.  $4^x=8000$ .  
Then, use the graph to find an estimate. Start at  $y=8000$  and move horizontally to the graph of the function. Then, move directly down to the  $x$ -axis. The value of  $x$  is estimated to be a little less than 6.5.
